

# Linux For Embedded Systems

## *For Arabs*

## Course 102: Understanding Linux

Ahmed ElArabawy

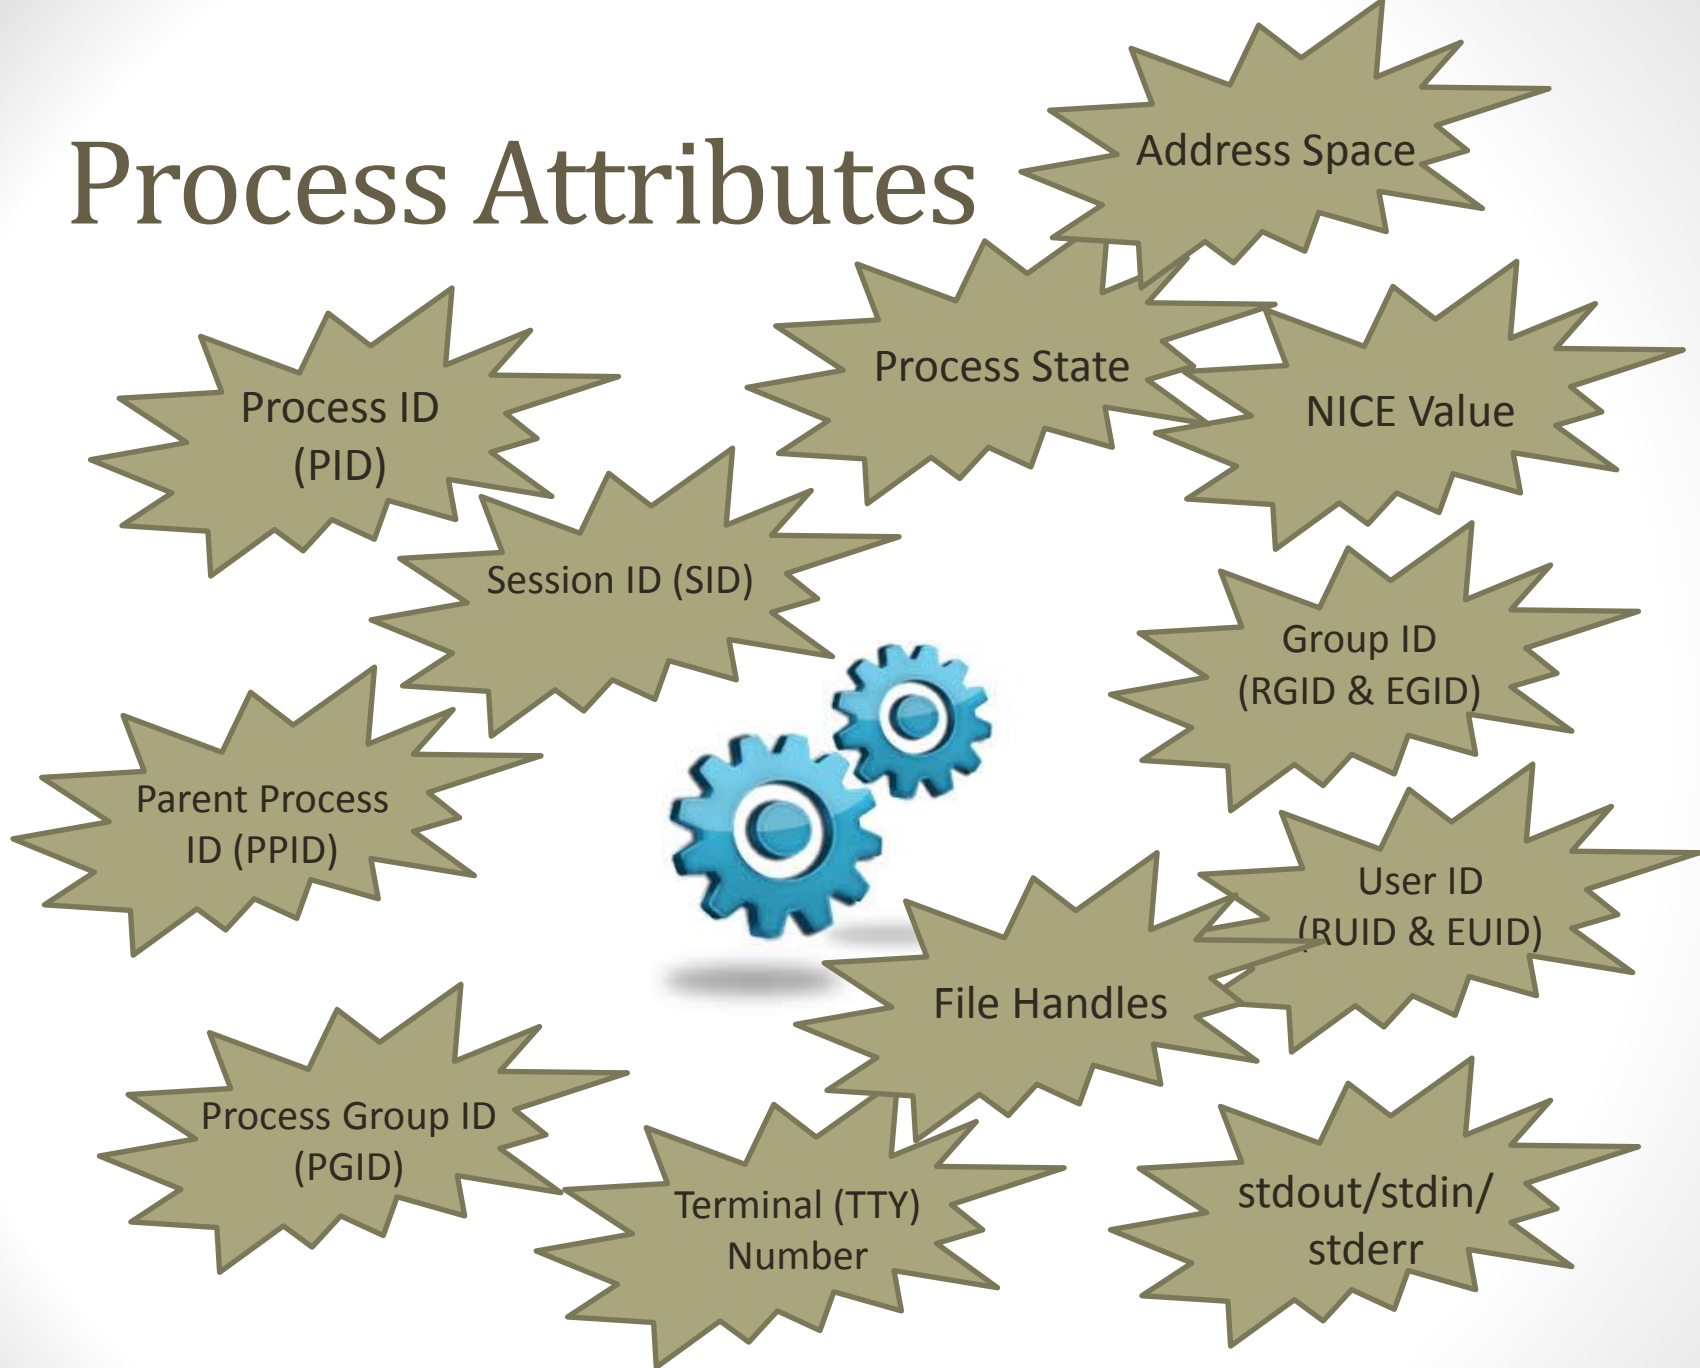

# Lecture 17:

## Process Monitoring

*On a UNIX system, everything is a file; if something is not a file, it is a process*

# Process Attributes

# Process Attributes

- Process Id (**PID**)
  - A unique identification number used to refer to the process
- Parent Process ID (**PPID**)
  - The process ID of the parent process
- Process Group ID (**PGID**)
  - The ID for the process group that this process belong to
  - Will be equal to **PID** if the process is a Process Group Leader
- Session ID (**SID**)
  - The ID for the session that this process belong to
  - The same for the **PID** if this process is the Session Leader
- Terminal Number
  - The number of the terminal that is associated with the process
  - Only applicable for interactive processes
  - Batch processes and Daemons have the value of 0

# Process Attributes

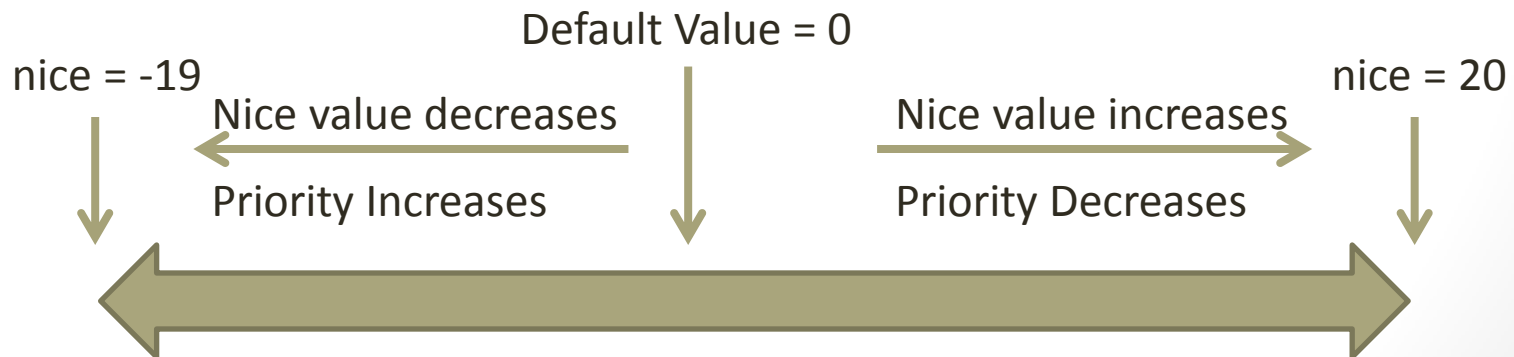

- Owner User ID
  - There are two user IDs for the process
    - Real User ID (**RUID**): the user who started the process
    - Effective User ID (**EUID**): the user whose privileges will be inherited by the process when accessing resources
    - By default **RUID** and **EUID** has the same value
- Owner Group ID
  - Similar to user ID, there are two Group IDs
    - Real Group ID (**RGID**): The primary group of the user who started the process
    - Effective Group ID (**EGID**): The Group ID whose privileges are inherited by the process when accessing system resources
    - By default **RGID** and **EGID** has the same value

# Process Priority

- Each process will have a priority value
- The process priority affects the scheduler behavior in the Linux Kernel
- A Process with higher priority may,
  - Receive more processor time by the kernel
  - Get scheduled more often
  - Preempt processes with lower processes
- Process priority is defined by,
  - User Controlled value (*nice* Value)
  - Kernel calculated value (based on the process behavior)
    - Processing bound
    - I/O bound

# The “nice” Value

- This is a value between -19 to 20 assigned by the user
- The kernel uses this value as a factor in calculating the process priority
- The higher the “nice” value of the process, the more it is accommodating other processes (less aggressive), which means lower priority

# Set Process Priority (nice Command)

**\$ nice -<value> command**

**\$ nice -n <value> command**

This command sets the nice value to manipulate the process priority

- To increase priority, **nice** should be decreased and vice versa
  - **nice** value vary between -20 to +19
  - Default **nice** value is "0"
- Example:
  - To set **nice** to value 5 for a new process,  
***\$ nice -5 processCommand &***  
***\$ nice -n 5 processCommand &***
  - To set nice to value -10 for a new process  
***\$ nice --10 processCommand &***  
***\$ nice -n -10 processCommand &***
- Note: non-root users can only do 1-19 nice values

# Modify Process Priority (renice Command)

**\$ renice <value> <pid of process>**

This command changes the “**nice**” value of a process

Example:

***\$ renice 10 1002***

- Note,
  - Non-root users can only increase the processes **nice** value (decrease its priority)
  - The passed value is the new **nice** value and not a increment/decrement value

# DISPLAY PROCESS INFORMATION & SYSTEM RESOURCE USAGE

# Displaying Process Info

Command	Function
<b><i>\$ ps</i></b>	Display Process Static Information
<b><i>\$ pstree</i></b>	Display Process Hierarchy
<b><i>\$ top</i></b>	Display Resource usage by processes
<b><i>\$ vmsat</i></b>	Display System Resource Usage
<b><i>\$ xload</i></b> <b><i>\$ tload</i></b>	System load average (in Graphical fashion)
<b><i>\$ free</i></b>	Display of Memory Usage (used/free)
<b><i>\$ time</i></b>	Measuring Running Time of a Command
<b><i>\$ uptime</i></b>	Measuring System Uptime

# Display Process Info (ps Command)

**\$ ps <options>**

Display Information about the running processes

- The **ps** command is a very powerful and diverse command
- It has a lot of options to change the ways to display process info,
  - Some options are used to define the scope of which processes to show
  - Other options are used to define the format of the listing and which information to show
- we will go through the common forms for the command

# The **ps** Command

## Defining Scope

***\$ ps***

- Display info about processes under the current shell

***\$ ps -e***

***\$ ps -A***

- Display all processes in the system

***\$ ps a***

- Display all processes in the system except those which are not attached with a terminal

***\$ ps ax***

- Display all processes in the system including those which are not attached with a terminal

# Defining Format

- You can use different options to define the format of the output (what columns to show)
- Some of the common usages

***\$ ps -f***

***\$ ps -F***

- To specify which fields to show use “-o” option

***\$ ps -o pid,ppid,pgid,sid,command***

# Showing Threads

- To show threads for multithreaded applications, use one of the following options

*\$ ps -H*

*\$ ps -L*

*\$ ps -T*

*\$ ps -m*

# Common Practices

- There are hundreds of processes running in the system
- A common practice, is to do a full listing and pipe the output to a search filter to limit the list to what we are interested in
  - \$ ps -ef | grep root***
    - This shows all processes owned by the root user
  - \$ ps aux | grep "pts/2"***
    - This shows all processes attached to the tty pts/2
- There are a lot of options for scope and format. For a special need, it is advised to refer to the man page for the command
  - \$ man ps***

```

Load Average

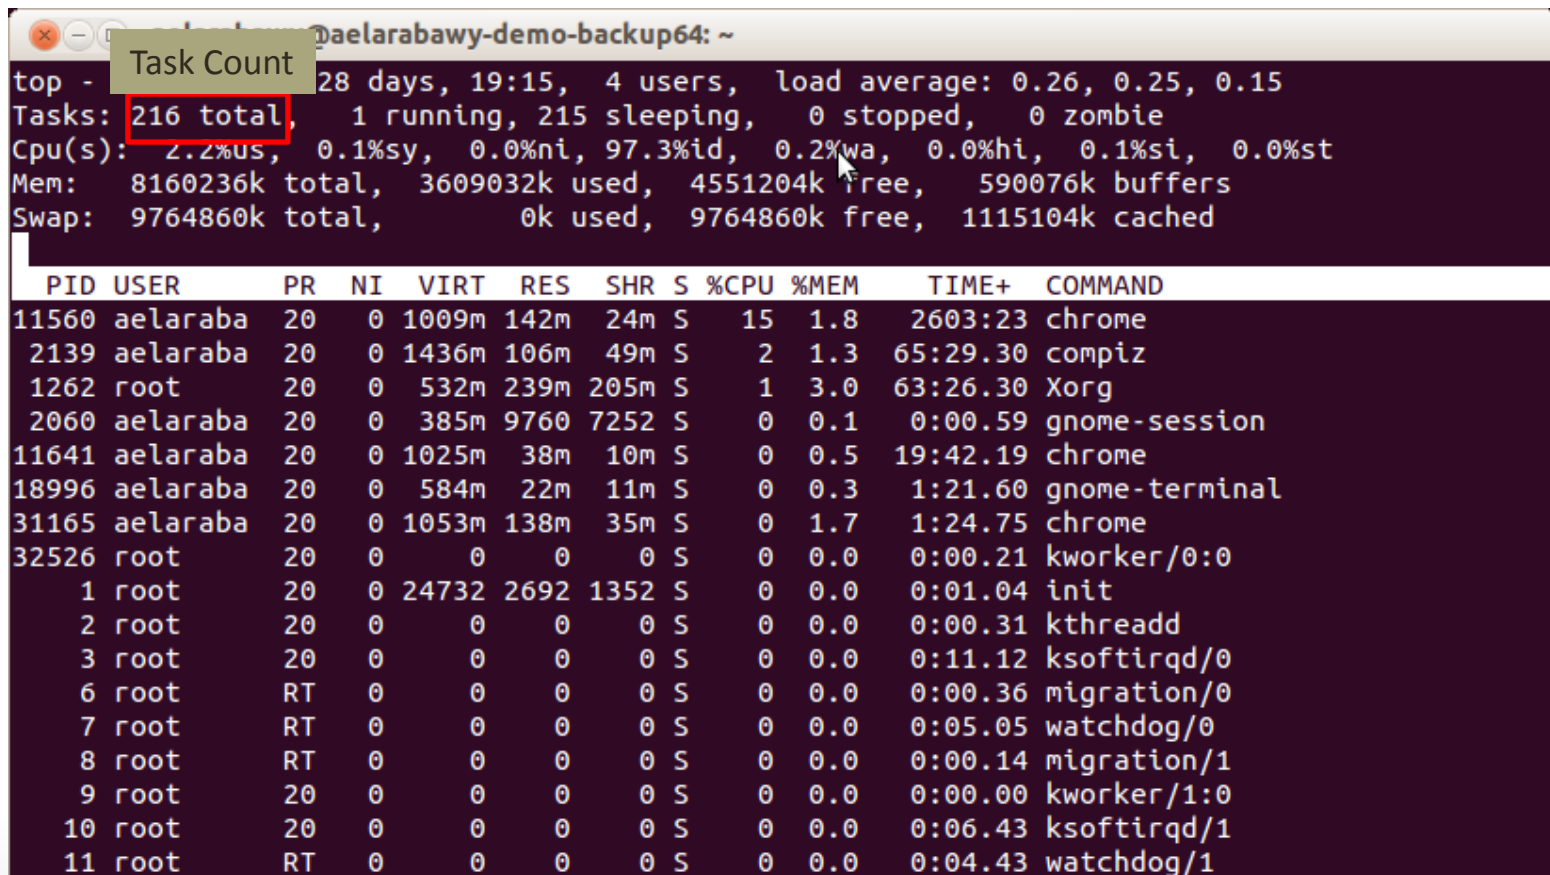

1 = Load can make a CPU fully loaded  
If we are running with a single core .... Then it is 100% Loaded  
But in case of multiple core,  
2 Cores: On average, each is 50% loaded  
4 Cores: On average, each is 25% loaded  
Note: we don't know how load is distributed among the cores

^C  
aelarabawy@aelarabawy-demo-backup64:~$
```

# Measuring Running Time (time Command)

**\$ time <command>**

- Displays elapsed time running a command

```
aelarabawy@aelarabawy-demo-backup64: ~  
aelarabawy@aelarabawy-demo-backup64:~$ time tree > tree-file  
  
real    0m0.559s  
user    0m0.308s  
sys     0m0.248s  
aelarabawy@aelarabawy-demo-backup64:~$
```

This will result in

- Output of the command
- Real time → total time = user + system + waiting
- User time → User space time
- System time → system time

Note that the waiting time stands for the time the command spent waiting due to :

- I/O blocking
- Scheduling and multi-tasking (context switching)

# Measuring System Uptime (uptime Command)

## \$ uptime

- Displays system up-time and load average

```
aelarabawy@aelarabawy: ~  
aelarabawy@aelarabawy:~$ uptime  
10:33:56 up 88 days, 17:39, 16 users,  load average: 0.29, 0.27, 0.29  
aelarabawy@aelarabawy:~$
```

## Load average,

- Calculated for the last 1, 5, and 15 minutes
- Note that average load is not normalized to number of system cores,  
For example, a load average of 1 means,
  - Fully loaded CPU in case of a single core processor
  - 25% loaded CPU in case of a Quad-core processor

# Linux 4

## Embedded Systems
